Classification of Contacts in Protein Structures

1. Training Set and Data Retrieval

The first step of the project was retrieving the data from each .tsv file from the features_ring folder (1,807 PDBs in total) and storing it into a single DataFrame.

The data contained in each .tsv file consists in a tab-separated file available for each protein, in which each row represents a contact in the protein and each column represents a feature about that contact. The last column is the target label, specifying the interaction type.

Column position	Column name	Column meaning	Type of column	
1	pdb_id			
2	s_ch	chain		
3	s_resi	index	source residue identifie	
4	s_ins	insertion code	source residue identifi	
5	s_resn	name		
6	s_ss8	secondary structure 8 states (DSSP)		
7	s_rsa	relative solvent accessibility		
8	s_up	half sphere exposure up		
9	s_down	half sphere exposure down		
10	s_phi	phi angle		
11	s_psi	psi angle	: 1	
12	s_ss3	secondary structure 3 states (from angles)	source residue features	
13	s_a1	Atchley feature 1		
14	s_a2	Atchley feature 2		
15	s_a3	Atchley feature 3		
16	s_a4	Atchley feature 4		
17	s_a5	Atchley feature 5		
18	t_ch	chain		
19	t_resi	index	target residue identifie	
20	t_ins	insertion code		

21	t_resn	name	
22	t_ss8	secondary structure 8 states (DSSP)	
23	t_rsa	relative solvent accessibility	
24	t_up	half sphere exposure up	
25	t_down	half sphere exposure down	
26	t_phi	phi angle	
27	t_psi	psi angle	
28	t_ss3	secondary structure 3 states (from angles)	target residue features
29	t_a1	Atchley feature 1	
30	t_a2	Atchley feature 2	
31	t_a3	Atchley feature 3	
32	t_a4	Atchley feature 4	
33	t_a5	Atchley feature 5	
34	Interaction	interaction type	

Table 1.1: Training Set Description

Interaction Type	Count
HBOND	333,346
VDW	155,789
PIPISTACK	10,403
IONIC	9,068
SSBOND	866
PICATION	626
Unclassified	225,412

Table 1.2: Number of Examples by Bond Type.

2. Data Preprocessing

The preprocessing pipeline starts with removing all samples where the label is unavailable (to explain how we are reinputting them). Then, the missing values of each feature are replaced using the mean of the feature itself. Only numerical features are used.

It was considered to perform *Best Subset Selection* using Logistic Regression to determine which features are the most meaningful ones and the ones that are not influencing the decision much. However, all *Atchley* features are selected, so this step is skipped.

Scaling is then performed to standardize all the features to values between [0,1] to be then fed to the model.

The biggest criticality in the dataset is the heavy imbalance that is evident by looking at the number of contacts by interaction type. Notably, *Hydrogen Bonds* (HBOND) and *Van der Waals Contacts* (VDW) are the most numerous, which makes them overrepresented in the training set. The remaining contact types, instead, are underrepresented. Training a model with such unbalanced datasets is sure to yield poor performance, especially when evaluating the model on new unseen data.

To mitigate this issue, oversampling the underrepresented classes is applied to encourage the model to better learn the minority interactions. It is to be noted, however, that altering the dataset, especially by oversampling, can yield overly optimistic results in the training performance, which don't necessarily transfer to as good performances at inference time on new data. Therefore, the balancing process of the training set is performed carefully and conservatively.

The use of undersampling lead to greatly diminished performance distinguishing the majority classes (*Hydrogen Bonds and VDW Interactions*). For oversampling, *SMOTE* (*Synthetic Minority Oversampling TEchnique*) is used, which uses interpolation between samples to create new artificial data points. The sampling strategy is {IONIC: 20'000, PIPISTACK: 10'000, PICATION: 20'000, SSBOND: 10'000}

3. Model

3.1. Deep Neural Network

The model created to classify residue-residue contacts is a *Deep Neural Network* for multiclass classification. The Deep Learning library of choice is *Keras*, a very commonly used open-source library that acts as an interface for *TensorFlow*.

The first step to be carried out is the encoding of the label of each sample into an identity vector, using a common practice called "One-Hot Encoding". This ensures that each class is uniquely identified and independent of the others. It helps the neural network to better understand the categorical nature of the data and prevents any ordinal relationship assumptions between the classes.

One-Hot Encoding is also performed to then set the number of neurons of the output layer to be equal to the number of classes in the dataset, in order to train each output neuron to determine the probability $P(C_i | \text{data})$, with $\sum P(C_i | \text{data}) = 1$. Therefore, the output layer represents the probability distribution of a contact being of a certain type.

Although the model is a relatively small Deep Neural Network with fully connected layers, overfitting is mitigated using L2 Regularization (Weight Decay) on each Dense layer, and Early Stopping monitoring the loss progression over the epochs. These two techniques

provide better generalization performance. The use of random dropout of neurons after each hidden layer was also tested, without any meaningful improvement on final test performance.

3.2. Model Details and Hyperparameters

Hyperparameters			
Batch Size	16'000		
Weight Initialization	$Xavier \; ({\tt GlorotNormal})$		
Loss Function	Categorical Cross-Entropy		
Optimizer	Adam		
Hidden Layers: Activation Function	ReLU		
Output Layer: Activation Function	Softmax		

Table 3.2.1: Model's hyperparameters (Keras)

Layer Type	Output Shape	Param #
Dense	128	768
Dense	128	16512
# Total Parameters		67,590

Table 3.2.2: Model's architecture (Keras)

4. Results

4.1 Performance

Testing data consisted of 51,608 examples, or 10% of unbalanced non-preprocessed data. Particular attention was put into not having any leak of the oversampled training set data into the test set. well behaved loss (figure 4.1) and AUC (figure 4.2) histories are evidence of successful model improvement. As demonstrated by the accompanying metrics, the model preforms better that the provided Naive Bayes classifier, achieving on the test set a Total Accuracy of 71%, ROC AUC of 0.79 (figure 4.2), and a Matthews Correlation Coefficient of 0.38.

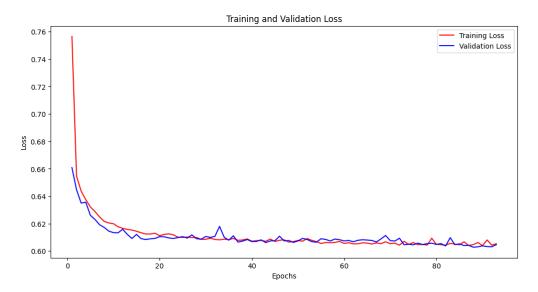

Figure 4.1: Training and Validation Loss

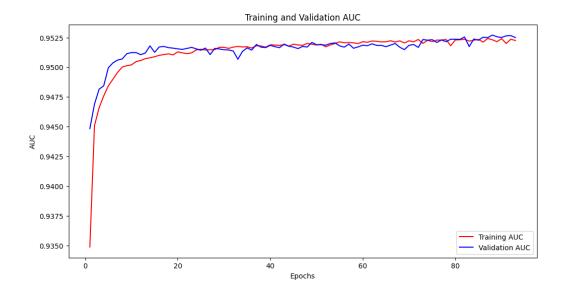

Figure 4.2: Training and Validation AUC

	precision	recall	f1-score	support
HBOND	0.77	0.85	0.81	33656
IONIC	0.46	0.26	0.33	916
PICATION	0.05	0.60	0.09	63
PIPISTACK	0.39	0.99	0.56	1050
SSBOND	0.43	1.00	0.60	88
VDW	0.61	0.41	0.49	15735
macro avg	0.45	0.68	0.48	
weighted avg	0.71	0.70	0.70	51508

Table 4.1: Test Performance by Interaction Type

4.2 Issues

In attempt to address poor precision on minority classes, many alternative approaches were tested, including:

- Ensemble Methods: One-vs-One, One-vs-All, and Model Stacking
- Different architectures
- Different regularization techniques: Dropout, Weight Decay, Batch Normalization
- Balancing

Nonetheless, it was found that ordinary Deep Neural Networks had the best compromise between minority class and majority class precision. Models that showed improvements in one of these areas consistently suffered in the other.

Implementing dataset balancing greatly improved model recall on minority classes. This would indicate that the model is effectively learning information about the classes. However, these classes still suffer from poor precision with resampling likely attributed to the relatively extremely low unique examples not allowing for a good representation of the class to be learned. The model additionally showed great sensitivity to undersampling, quickly leading to diminished ability to distinguish *Hydrogen Bonds* and *VDW Interactions*, the largest influence on total accuracy. The final model relied primarily on having the minority classes oversampled. Though, oversampling additionally quickly lead to poor generalization on minority classes due to the extremely low number of unique examples making learning a good representation of the classes difficult.

5. Usage

To predict the contacts of a new PDB file using the pretrained model, run the following command in your terminal, using arguments:

```
python3 contact_net.py --inference --pdb your_pdb_id
```

To perform retraining or the model, instead, run:

```
python3 contact_net.py --train
```

The full documentation of the software is available in the GitHub repository at the following \underline{link} .
